Data acquisition and analysis without the MACSQuant® Analyzer

General instructions for MACSPllex Cytokine Kits

Data acquisition and analysis of MACSPllex Cytokine Kits with another instrument than the MACSQuant® Analyzer

MACSPllex Cytokine Kits are designed for measuring cytokine amounts in a single sample. A prerequisite for the performance of MACSPllex Assays is a flow cytometer with a blue (e.g., 488 nm) and a red (e.g., 635 nm) laser and the ability to detect FITC, PE, and APC. For detailed information on how to run MACSPllex Cytokine Kits on a MACSQuant® Analyzer or MACSQuant Analyzer 10, please refer to the special protocol “Data acquisition and analysis of MACSPllex Cytokine Kits using the MACSQuant® Analyzer Express Modes” available at the respective product page at www.miltenyibiotec.com. Please note that MACSPllex Cytokine Kits cannot be run on a MACSQuant VYB. The instructions below apply for the use of other flow cytometers featuring the required optical configuration.

General setup procedure

In order to setup flow cytometers other than the MACSQuant Analyzer and MACSQuant Analyzer 10, MACSPllex (MPx) Setup Beads are provided in the kit.

1. Start the flow cytometer according to the manufacturer’s instructions.
2. Open a new protocol.
3. Create two dot plots and one histogram:
   - Forward scatter versus side scatter – dot plot
   - FITC (525 nm) versus PE (585 nm) – dot plot
   - APC (655 nm) – histogram
4. Set all scatter axes to log scale and all fluorescence axes to hlog scale.

Note: The dot plots in the following example include hlog scales. However, if this option is not available on your flow cytometer, log scales are also applicable.

Figure 1: Analysis template, including two dot plots (A and B) and one histogram (C).
5. Set all compensation to zero.
6. Resuspend the MPx Setup Beads by vortexing for at least 30 seconds before use.
7. Dilute MPx Setup Beads by dispensing one drop in 1 mL of MACSPlex buffer.
8. Run the MPx Setup Bead sample in the setup mode. If not available, choose a similar mode that allows the adjustment of all required parameters while running the MPx Setup Bead sample.
9. Adjust the forward scatter (FSC) and side scatter (SSC) PMT voltages and trigger or threshold (if applicable), so that the bead population is visible in the respective FSC/SSC dot plot.
10. Place a gate around singlets.
11. Activate the singlet gate in the FITC channel versus PE channel dot plot.
12. Adjust PMT voltages for the FITC and PE channels. Ensure that the bead population is placed in the center of the plot.
13. Place a gate around the bead population.
14. Activate gate P2, containing only MPx Setup Bead singlets, in the APC histogram.
15. Ensure that the APC signal of the gated bead population shows a typical negative population peak (e.g., similar to unlabeled cells). If this is not the case, adjust the PMT voltage of the APC channel accordingly.
16. Save the instrument settings.

There is no compensation required. Please proceed directly to data acquisition.

**General acquisition procedure**

1. Change into acquisition mode.
2. Set the instrument to stop measuring once 300 events per cytokine have been acquired in the singlet gate (P1).
3. Delete the gate P2 that contains all MPx Setup Bead singlets in the FITC channel versus PE channel dot plot.
4. Always start the measurement with the MPx Standards, e.g., MPx Cytokine 12 Standard, beginning with 0 pg/mL and finishing with the highest standard. Process samples afterwards.

**Note:** Do not change any settings during measurement of the standards or samples.

**General data analysis procedure**

Load your acquisition files into a suitable analysis software. The following steps have to be applied to every sample of the MPx Standard dilution and every unknown sample. Begin the data analysis with MPx Standard dilutions before proceeding with samples.

1. Open a new protocol.
2. Create two dot plots:
   - Forward scatter versus side scatter
   - FITC channel (525 nm) versus PE channel (585 nm)
3. Set all scatter axes to log scale and all fluorescence axes to hlog scale.
4. Place a gate around the singlets in the forward scatter versus side scatter dot plot.

5. Activate the singlet gate (P1) in the FITC channel versus PE channel dot plot.

6. Place a gate around every MPx Capture Bead population.

7. Create a statistics table displaying the APC medians for each MPx Capture Bead population. Apply the same coding of MPx Capture Bead populations as shown in figure 7.

Note: Your results will be more reliable, if your analysis software allows you to select the APC median or geometric mean instead of the mean.

Figure 7: Example of a FITC channel versus PE channel dot plot of the MPx Capture Bead populations with activated singlet gate using the MACSPlex Cytokine 12 Kit, human. The appearance of the dot plots might vary depending on the used flow cytometer and analysis software. However, the overall arrangement of the MPx Capture Bead populations should be similar to the example shown here.

Note: The dot plots in the following example include hyperlog scales. However, if this option is not available on your flow cytometer, log scales are also applicable.
Calculation of cytokine concentrations

1. After applying the analysis protocol to all acquired MPx Standard dilutions and samples, transfer the APC medians into a spreadsheet of a suitable software.
2. Create a standard curve for every measured cytokine using the APC medians of the MPx Standard dilutions.
3. Calculate the concentration of each measured cytokine using the respective standard curve.
